1 Introduction

1.1 Math Information Systems

[1] EdN:1

[1] EdNote: why are those special and different

1.2 Mathhub

1.3 Previous Implementation

Up until April 2018 the Mathhub frontend was realized with Drupal. Drupal is an open source content-management framework used by millions of different websites. Dealing with user interactions were handled by JavaScript modules in the JOBAD framework [KW14].

But in April 2018 a critical security flaw in the versions 6 to 8 went public. The problem was that the Drupal core in these versions accepts request parameters without any validation. This means the core processes any input from anybody [Tun18]. To exploit this weakness an attacker doesn't even need to log in or have any other privileges on a vulnerable website [McC18]. With this flaw it is possible to inject malicious code and compromise a website in multiple ways. This can be used to access, change and delete private data and create backdoors to make future attacks possible. The Drupal community called this weakness "Drupalgeddon2" while its official name was "CVE-2018-7600". Some code that was injected installed the program XMRig Monero miner, which is a cryptocurrency mining program, as well as deleting other mining programs on the compromised system [Kum18]. The National Institute of Standards (NIST) and Technology gave Drupal a "Highly Critical" Rating because of this vulnerability [NIS]. After this flaw was discovered a patch was published and a warning to update every website that used a vulnerable version was given.

Since there have been multiple flaws in Drupal before that compromised Mathhub, the decision to stop using it and rebuild Mathhub from the ground up to not be affected by future attacks, was made.

2 State of the art

2.1 Building an interactive Frontend

Before starting to build a completely new Mathhub fronten a different web framework had to be chosen.

Polymer is an open source JavaScript library developed and maintained by Google. It provides a set of features that make creating custom elements, that work like standard web components, easy. It is used for several Google services for example Youtube, Google Earth, Google Play Music etc. as well as Netflix, Electronic Arts and many other companies. [Wika]

Another open source web framework from Google is **Angular**. This TypeScript library has framework architectures that simplifies the development of new web applications. It also has Angular Material. A collection of UI components that work in browsers, on mobile and desktop. [Ang]

After using Angular on several Google projects, Evan You decided to create his own JavaScript framework called **Vue.js** [Wikb] Depending on the

project it can be scaled between a framework and a library. Vue.js separates its view layer library from its support libraries for complex applications, to create an easy approach to the framework. [Git]

In the end the decision was made to use **React** developed by Facebook. Further details about React and how it is used can be found in section 3.

2.2 Math Information Systems

- MathNet
- mathoverflow
- Wikidata
- Wikipedia

3 Preliminaries

3.1 The core concept of React

React is an open source JavaScript library owned and maintained by Facebook. It was created to build interactive user interfaces (UI). For example it is used for Facebook and Instagram. What makes React unique is its use of a virtual Document Object Model (DOM). The concept of the virtual DOM is that when updating a website not everything is rendered again. React computes the differences between the last and the next page and only changes the necessary parts. On top of that it has conditional rendering which means that an item will only be rendered if it is shown. The advantage of virtual and conditional rendering is that this makes updating a website fast, but it comes with high RAM costs. The actual interface is made up of many different elements and components. Since a website that uses React can have many different features it is helpful to build new components. [Inca]

3.2 Building new components in React

React already has a large library with a lot of different components, but it is often necessary to make new ones that have the desired functionality. In JavaScript new components can be implemented by creating either a function or a class. Their input variables are called props and can only be read. Components return React elements that are ready to be rendered. Naturally a component can grow big rather quickly. Luckily it is possible to use components inside other components. This comes with the advantage that they can be reused in many different locations. The difference between creating a new component as a function and as a class is that a class can have a private internal state, which can be updated an any time. Since props

are read-only, updating the state can only affect lower components. If it is necessary to also change something in a higher component it is possible to "lift up" the state. This means adding the state that causes the change to the state of the component on a higher level and giving it back to the lower levels as a prop. If the update should affect a component on the same level creating a new component with that state that consist of all the one that are affected will make this possible. [Incb]

3.3 MMT and OMDoc

- OMDoc: XML format of how a uniform language for knowledge should be designed
- MMT is a scalable Module System for Mathematical theories
- MMT is a framework for knowledge representation using formal languages
- individual features are defined as reusable modules -¿ create individual languages
- high degree of abstraction of advanced algorithms
- archives: correspond to software projects; work flows for languages in MMT
- groups / libraries: collection of archives
- module: theory or view
- view: relations between theories
- theory: defined by declarations
- declaration: constants and rules
- groups and archives just for narration
- modules and declarations are actual content [Rab]

4 The Architecture of Mathhub

[2] EdN:2

- React for building pages and interaction with the backend/MMT
- Semantic UI React for theming

[2] EdNote: look for author and user pictures

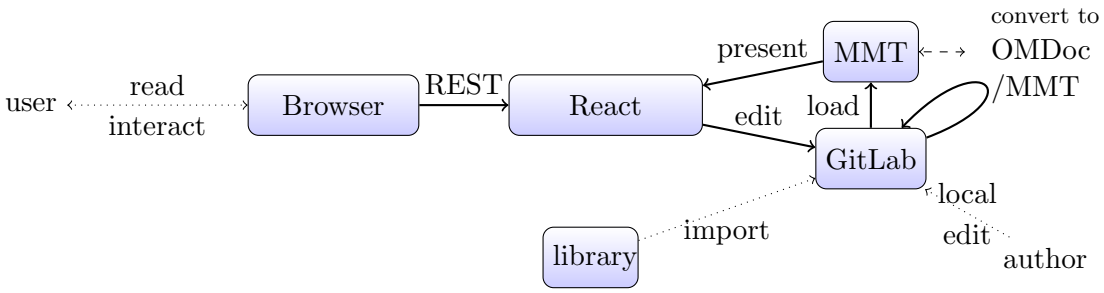

Figure 1: Mathhub architecture

- In the web-based system, semantic services (notation-based, presentation, definition lookup, relational navigation, dependency management, etc.) are provided by MMT and are made available to the user, primarily by dedicated React components.
- Gitlab used for versioned storage of the content documents, and organizes them into repositories
- conversion to OMDoc
- OMDoc functionalities and semantics for presentation

4.1 Mathhub Routes

- Routes to every step in the MMT Library
- groups and archives no actual content only for navigation purposes
- Documents are a list of actual content like theories and declarations
- own page for Library → archives → documents
- some Legal stuff (Licenses and Privacy Policy)
- Log

With the huge mathematical library of theories there are a lot of technical terms. The glossary is a collection of these expressions. There wouldn't be much value in to just having a collection without any additional features. So the glossary also provides a definition for each term. Many different authors have contributed to the theories, so it can happen that there are different terms that share a meaning. These synonyms can also be found in the glossary. Since many theories exist in multiple languages it makes sense to have a glossary available for the used languages. Currently the biggest collection of terms are in the English glossary, followed by German

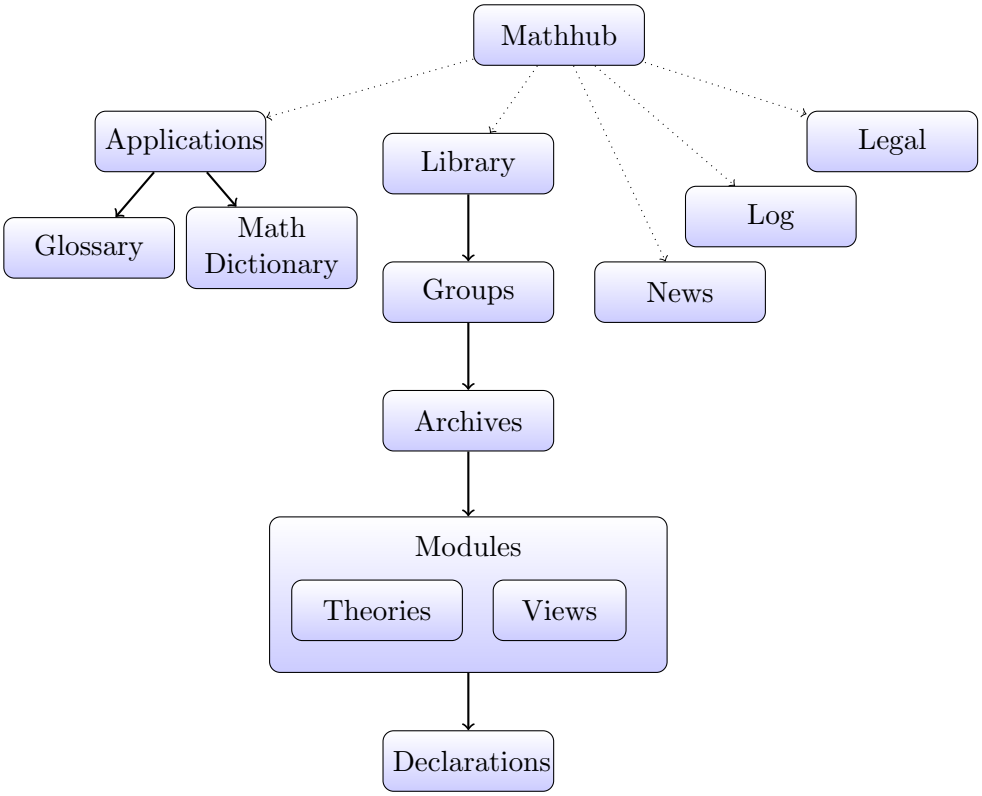

Figure 2: Mathhub components

and French. Smaller collections for Turkish and Romanian are also available as well as simplified and traditional Chinese.

Most of the times a user does not want to browse through the gigantic glossary to just find a single term. This is the reason why the Math Dictionary is a useful extension of the glossary. The main purpose of the Math Dictionary is to translate a term into another language.

4.2 Layout

- Header: Menu with routes to Home, Applications (Glossary, Math Dictionary), Help and About
- Footer: Developed, Institutions, Funding, Logger and Legal [3] EdN:3
- body dependent on page

4.3 Communication with the Backend

- many clients communicate with a (MMT) backend

[3] EdNote: Screenshots

- Rest
- JSON

5 Mathhub Components

[4] [5] [6]

EdN:4
EdN:5
EdN:6

5.1 Groups

- link to source on gl.mathhub.info
- description text of the group
- list of archives in the group with short teaser
- every archive is a React component

5.2 Archives

- link to source on gl.mathhub.info
- description text of the group
- list of the documents in the archive

5.3 Documents

- extendable modules
- extension shows declarations like structure and constants
- opaque elements: text for humans

5.4 Statistics

- groups, archives and documents can have statistics
- visible by button
- popup for explanation of keywords

[4] EdNote: what exactly have I done in the Frontend with these

[5] EdNote: don't go into to much detail about the implementation; eg entry has own react component is okay but don't talk about cards and stuff

[6] EdNote: get some nice screen shots

6 The Applications of Mathhub

6.1 Glossary

- Different language tabs
- only language relevant terms are rendered

In the frontend it is possible to change languages by either changing the language tab or clicking on a language button inside an entry. If there is a button with a different language available, this means this particular entry also exists in this language. The definition of a term is not immediately shown to create a better overview. To makes the definition visible the user can click on the entry.

6.2 Math Dictionary

To translate a term with the help of the Math Dictionary so the user has to select the language in which the term currently is and also the language to which should be translated into. Pressing the "translate" - button sends a translation request to the server. Until the servers responds the message "translating" is shown and the button is disabled to prevent sending to many translation requests. If a translation exists then the translated term, its definition and potential synonyms are shown. By selecting the same language for "from" and "to" the Math Dictionary can also be used to get the definition for an expression without searching the glossary.

7 Conclusion

8 Future Work

8.1 TGView

8.2 MathWebSearch

8.3 Subset Frontends

8.4 Issue report: Mathhub and content
